Areal unit data

4

NEON Applied Bayesian Regression Spatio-temporal Workshop

Areal unit data

## Key Issues

- Is there *spatial pattern*? *Spatial pattern* implies that observations from units closer to each other are more similar than those recorded in units farther away.
- Do we want to *smooth* the data? Perhaps to adjust for low population sizes (or sample sizes) in certain units? How much do we want to smooth?
- Inference for *new* areal units? Is prediction meaningful here? If we modify the areal units to new units (e.g. from zip codes to county values), what can we say about the new counts we expect for the latter given those for the former? This is the Modifiable Areal Unit Problem (MAUP) or Misalignment.

5

NEON Applied Bayesian Regression Spatio-temporal Workshop

Proximity matrices

- $W$ , entries  $w_{ij}$ , ( $w_{ii} = 0$ ); choices for  $w_{ij}$ :
  - $w_{ij} = 1$  if  $i, j$  share a common boundary (possibly a common vertex)
  - $w_{ij}$  is an *inverse* distance between units
  - $w_{ij} = 1$  if distance between units is  $\leq K$
  - $w_{ij} = 1$  for  $m$  nearest neighbors.
- $W$  need not be symmetric.
- $\tilde{W}$ : standardize row  $i$  by  $w_{i+} = \sum_j w_{ij}$  (row stochastic but need not be symmetric).
- $W$  elements often called "weights"; nicer interpretation?

6

NEON Applied Bayesian Regression Spatio-temporal Workshop

- Note that proximity matrices are user-defined.
- We can define distance intervals,  $(0, d_1]$ ,  $(d_1, d_2]$ , and so on.
  - First order neighbours: all units within distance  $d_1$ .
  - First order proximity matrix  $W^{(1)}$ . Analogous to  $W$ ,  $w_{ij}^{(1)} = 1$  if  $i$  and  $j$  are first order neighbors; 0 otherwise.
  - Second order neighbors: all units within distance  $d_2$ , but separated by more than  $d_1$ .
  - Second order proximity matrix  $W^{(2)}$ ;  $w_{ij}^{(2)} = 1$  if  $i$  and  $j$  are second order neighbors; 0 otherwise
  - And so on...

- There are analogues for areal data of the empirical correlation function and the variogram.
- Moran's  $I$ : analogue of lagged autocorrelation

$$I = \frac{n \sum_i \sum_j w_{ij} (Y_i - \bar{Y})(Y_j - \bar{Y})}{(\sum_{i \neq j} w_{ij}) (\sum_i (Y_i - \bar{Y})^2)}$$

$I$  is not supported on  $[-1, 1]$ .

- Geary's  $C$ : analogue of Durbin-Watson statistic

$$C = \frac{(n-1) \sum_i \sum_j w_{ij} (Y_i - Y_j)^2}{\sum_{i \neq j} w_{ij} \sum_i (Y_i - \bar{Y})^2}$$

- Both are asymptotically normal if  $Y_i$  are i.i.d., the first with mean  $-1/(n-1)$  and the second with mean 1.
- Significance testing using a Monte Carlo test, permutation invariance

- The *areal correlogram* is a useful tool to study spatial association with areal data.
- Working with  $I$ , we can replace  $w_{ij}$  with  $w_{ij}^{(1)}$  taken from  $W^{(1)}$  and compute  $\rightarrow I^{(1)}$
- Next replace  $w_{ij}$  with  $w_{ij}^{(2)}$  taken from  $W^{(2)}$  and compute  $\rightarrow I^{(2)}$ , etc.
- Plot  $I^{(r)}$  vs.  $r$
- If there is spatial pattern, we expect  $I^{(r)}$  to decline in  $r$  initially and then vary about 0.

- To smooth  $Y_i$ , replace with  $\hat{Y}_i = \frac{\sum_j w_{ij} Y_j}{w_{i+}}$  Note:  $K$ -nearest neighbours (KNN) regression falls within this framework.
- More generally,
 
$$(1 - \alpha)Y_i + \alpha \hat{Y}_i$$
 Linear (convex) combination, shrinkage
- Model-based smoothing, e.g.,  $E(Y_i | \{Y_j, j = 1, 2, \dots, n\})$

- First, consider  $\mathbf{Y} = (y_1, y_2, \dots, y_n)$  and consider the set  $\{p(y_i | y_j, j \neq i)\}$
- We know  $p(y_1, y_2, \dots, y_n)$  determines  $\{p(y_i | y_j, j \neq i)\}$  (full conditional distributions)
- ??? Does  $\{p(y_i | y_j, j \neq i)\}$  determine  $p(y_1, y_2, \dots, y_n)$ ? If so, we call the joint distribution a **Markov Random Field**.
- In general we cannot write down an arbitrary set of conditionals and assert that they determine the joint distribution. Example:

$$Y_1 | Y_2 \sim N(\alpha_0 + \alpha_1 Y_2, \sigma_1^2)$$

$$Y_2 | Y_1 \sim N(\beta_0 + \beta_1 Y_1^3, \sigma_2^2)$$

- The first equation implies that  $E[Y_1] = \alpha_0 + \alpha_1 E[Y_2]$ , i.e.,  $E[Y_1]$  is linear in  $E[Y_2]$ . The second equation implies that  $E[Y_2] = \beta_0 + \beta_1 E[Y_1^3]$ , i.e.  $E[Y_2]$  is linear in  $E[Y_1^3]$ . Clearly this isn't true in general. Hence no joint distribution.

- Also  $p(y_1, \dots, y_n)$  may be improper even if all the full conditionals are proper.

$$p(y_1, y_2) \propto \exp\{(y_1 - y_2)^2\}$$

But  $p(Y_2 | Y_1) \propto N(Y_2)$  and  $p(Y_1 | Y_2) \propto N(Y_2, 1)$ . Yet the joint distribution is improper.

- Compatibility: **Brook's Lemma**. Let  $\mathbf{y}_0 = (y_{10}, \dots, y_{n0})$  be any fixed point in the support of  $p(\cdot)$ .

$$p(y_1, \dots, y_n) = \frac{p(y_1 | y_2, \dots, y_n) p(y_2 | y_{10}, y_3, \dots, y_n)}{p(y_{10} | y_2, \dots, y_n) p(y_{20} | y_{10}, y_3, \dots, y_n)} \dots \frac{p(y_n | y_{10}, \dots, y_{n-1,0})}{p(y_{n0} | y_{10}, \dots, y_{n-1,0})} p(y_{10}, \dots, y_{n0}).$$

If LHS is proper, the fact that it integrates to 1 determines the normalizing constant!

- Suppose we want:

$$p(y_i | y_j, j \neq i) = p(y_i | y_j \in \partial_i)$$

- When does the set  $\{p(y_i | y_j \in \partial_i)\}$  uniquely determine  $p(y_1, y_2, \dots, y_n)$ ?
- To answer this question, we need the following important concepts:
  - Clique**: A clique is a set of cells such that each element is a neighbor of every other element. We use notation  $i \sim j$  if  $i$  is a neighbor of  $j$  and  $j$  is a neighbor of  $i$ .
  - Potential**: A potential of order  $k$  is a function of  $k$  arguments that is exchangeable in these arguments. The arguments of the potential would be the values taken by variables associated with the cells for a clique of size  $k$ .

- For clique size say 2,  $i \sim j$  means  $j \sim i$
- For continuous data:  $Q(y_i, y_j) = y_i y_j \quad (\Leftrightarrow (y_i - y_j)^2)$
- For binary data:
  - $Q(y_i, y_j) = I(y_i = y_j) = y_i y_j = (1 - y_i)(1 - y_j)$
- Cliques of size 1  $\Leftrightarrow$  independence
- Cliques of size 2  $\Leftrightarrow$  pairwise difference form

$$p(y_1, y_2, \dots, y_n) \propto \exp\left\{-\frac{1}{2\tau^2} \sum_{i,j} (y_i - y_j)^2 I(i \sim j)\right\}$$

and therefore  $p(y_i | y_j, j \neq i) = N(\sum_{j \in \partial_i} y_j / m_i, \tau^2 / m_i)$ , where  $m_i$  is the number of neighbors of  $i$

- Gibbs distribution**:  $p(y_1, \dots, y_n)$  is a Gibbs distribution if it is a function of the  $y_i$ 's only through potentials on cliques:

$$p(y_1, \dots, y_n) \propto \exp\left\{-\gamma \sum_k \sum_{\alpha \in M_k} \phi^{(k)}(y_{\alpha_1}, \dots, y_{\alpha_k})\right\},$$

where  $\phi^{(k)}$  is a potential of order  $k$ ,  $M_k$  is the set of all cliques of size  $k$  and is indexed by  $\alpha$ , and  $\gamma > 0$  is a scale parameter.

- Hammersley-Clifford Theorem**: If we have a Markov Random Field (i.e.,  $\{p(y_i | y_j \in \partial_i)\}$  uniquely determine  $p(y_1, y_2, \dots, y_n)$ ), then the latter is a Gibbs distribution
- Geman and Geman (1984) result**: If we have a joint Gibbs distribution, then we have a Markov Random Field

### Conditionally Auto-Regressive (CAR) models

- Gaussian (autonormal) case

$$p(y_i | y_j, j \neq i) = N\left(\sum_j b_{ij} y_j, \tau_i^2\right)$$

- Using Brook's Lemma we can obtain

$$p(y_1, y_2, \dots, y_n) \propto \exp\left\{-\frac{1}{2} \mathbf{y}' D^{-1} (I - B) \mathbf{y}\right\}$$

where  $B = \{b_{ij}\}$  and  $D$  is diagonal with  $D_{ii} = \tau_i^2$ .

- Suggests a multivariate normal distribution with  $\mu_y = 0$  and  $\Sigma_Y = (I - B)^{-1} D$
- $D^{-1}(I - B)$  symmetric requires

$$\frac{b_{ij}}{\tau_i^2} = \frac{b_{ji}}{\tau_j^2} \text{ for all } i, j$$

- Returning to  $W$ , let  $b_{ij} = w_{ij}/w_{i+}$  and  $\tau_i^2 = \tau^2/w_{i+}$ , so

$$p(y_1, y_2, \dots, y_n) \propto \exp\left\{-\frac{1}{2\tau^2} \mathbf{y}' (D_w - W) \mathbf{y}\right\}$$

where  $D_w$  is diagonal with  $(D_w)_{ii} = w_{i+}$  and thus

$$p(y_1, y_2, \dots, y_n) \propto \exp\left\{-\frac{1}{2\tau^2} \sum_{i \neq j} w_{ij} (y_i - y_j)^2\right\}$$

- Caution**:  $(D_w - W)\mathbf{1} = \mathbf{0}$ . Intrinsic autoregressive (IAR) model; improper, so requires a constraint (e.g.,  $\sum_i y_i = 0$ )
- Not a valid data model, but only as a random effects model!

- With  $\tau^2$  unknown, what should be the power of  $\tau^2$ ?  
Answer:

$$p(y_1, y_2, \dots, y_n) \propto \left(\frac{1}{\tau^2}\right)^{(n-G)/2} \exp\left\{-\frac{1}{2\tau^2} \mathbf{y}'(D_w - W)\mathbf{y}\right\},$$

where  $G$  is the number of “islands” in the map. In fact,  $n - G$  is the rank of  $D_w - W$ .

- The **impropriety** can be remedied in an obvious way. Redefine the CAR as:

$$p(y_1, y_2, \dots, y_n) \propto |D_w - \rho W|^{1/2} \exp\left\{-\frac{1}{2\tau^2} \mathbf{y}'(D_w - \rho W)\mathbf{y}\right\},$$

where  $\rho$  is chosen to make  $D_w - \rho W$  non-singular. This is guaranteed if  $\rho \in (1/\lambda_{(1)}, 1)$ , where  $\lambda_{(1)}$  is the minimum eigenvalue of  $D^{-1/2} W D^{-1/2}$ . In practice, the bound  $\rho \in (0, 1)$  is often preferred.

To  $\rho$  or not to  $\rho$ ?

- **Advantages:**

- makes distribution proper
- adds parametric flexibility
- $\rho = 0$  interpretable as independence

- **Disadvantages:**

- why should we expect  $y_i$  to be a proportion of average of neighbors - sensible spatial interpretation?
- calibration of  $\rho$  as a correlation, e.g.,

$$\rho = 0.80 \text{ yields } 0.1 \leq I \leq 0.15,$$

$$\rho = 0.90 \text{ yields } 0.2 \leq I \leq 0.25,$$

$$\rho = 0.99 \text{ yields } I \leq 0.5$$

- So, used with random effects, scope of spatial pattern may be limited

Example of a hierarchical model with CAR effects.

- Consider the areal data **disease mapping** model:

$$Y_i | \mu_i \stackrel{\text{ind}}{\sim} Po(E_i e^{\mu_i}), \text{ where}$$

$$Y_i = \text{observed disease count,}$$

$$E_i = \text{expected count (known), and}$$

$$\mu_i = \mathbf{x}_i' \boldsymbol{\beta} + \phi_i; \text{ the } \mathbf{x}_i \text{ are explanatory variables}$$

- The  $\phi_i$  capture regional **clustering** via a conditionally autoregressive (CAR) prior,

$$\phi_i | \phi_{j \neq i} \sim N\left(\bar{\phi}_i, \frac{\tau^2}{m_i}\right), \text{ where } \bar{\phi}_i = \frac{1}{m_i} \sum_{j \in \partial_i} \phi_j;$$

$\partial_i$  is the set of “neighbours” of region  $i$ , and  $m_i$  is the number of these neighbours.

Comments on CAR models

- We specify  $\Sigma_y^{-1}$ , not directly modeling association
- $(\Sigma_y^{-1})_{ii} = 1/\tau_i^2$ ;  $(\Sigma_y^{-1})_{ij} = 0 \Leftrightarrow \text{cond'l independence}$
- Ad hoc prediction: If

$$p(y_0 | y_1, y_2, \dots, y_n) = N\left(\sum_j w_{0j} y_j / w_{0+}, \tau^2 / w_{0+}\right)$$

then  $p(y_0, y_1, \dots, y_n)$  well-defined but not CAR

- non-Gaussian case, binary data (**autologistic**)

$$p(y_i | y_j, j \neq i) \propto \exp\left\{\phi \sum_j w_{ij} I(y_i = y_j)\right\}$$

Simultaneous Auto-Regressive (SAR) models

- We may write the CAR model as:

$$\mathbf{y} = B\mathbf{y} + \boldsymbol{\epsilon} \Rightarrow (I - B)\mathbf{y} = \boldsymbol{\epsilon};$$

Since  $\mathbf{y} \sim N(\mathbf{0}, (I - B)^{-1}D)$ , we have

$$\boldsymbol{\epsilon} \sim N(\mathbf{0}, D(I - B)).$$

- Instead of letting  $\mathbf{y}$  induce the distribution of  $\boldsymbol{\epsilon}$ , let  $\boldsymbol{\epsilon}$  induce a distribution for  $\mathbf{y}$ . Letting  $\boldsymbol{\epsilon} \sim N(\mathbf{0}, \tilde{D})$ , where  $\tilde{D}$  is diagonal,  $\tilde{D}_{ii} = \sigma_i^2$  and let:

$$y_i = \sum_{j=1}^n b_{ij} y_j + \epsilon_i.$$

Assuming  $(I - B)^{-1}$  exists, we obtain:

$$\mathbf{y} \sim N\left(\mathbf{0}, (I - B)^{-1} \tilde{D} (I - B)^{-1}\right).$$

- Often we take  $B = \rho W$ . If  $\rho \in (1/\lambda_{(1)}, 1/\lambda_{(n)})$ , where  $\lambda_{(1)}$  and  $\lambda_{(n)}$  are the minimum and maximum eigenvalues of  $W$ . This ensures  $(I - \rho W)^{-1}$  exists.
- Alternatively, we can replace  $W$  with  $\tilde{W} = \{w_{ij}/w_{i+}\}$  where  $w_{i+}$  is the sum of the elements in the  $i$ -th row of  $W$ . Then  $|\rho| < 1$  ensures existence of  $(I - \rho \tilde{W})^{-1}$ .
- Often SAR models are also applied to point-referenced data where  $W$  is taken to be the inter-point distance.

- Two variants:

- The SAR “lag model”:

$$\mathbf{y} = B\mathbf{y} + X\boldsymbol{\beta} + \boldsymbol{\epsilon}.$$

- The SAR “residual” or “error model”:

$$(I - B)(\mathbf{y} - X\boldsymbol{\beta}) = \boldsymbol{\epsilon}; \Rightarrow \mathbf{y} = B\mathbf{y} + (I - B)X\boldsymbol{\beta} + \boldsymbol{\epsilon}.$$

- SAR models are well suited to maximum likelihood estimation but not at all for MCMC fitting of Bayesian models. Because it is difficult to introduce SAR random effects (in the CAR framework this is easy because of the hierarchical conditional representation).
